        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}
```

Quel est le problème ? 

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

Quel est le problème ? 

**⚠️ Si l'on exécute cette function, le statut passé à `notify` et `incrementCounter` sera toujours le même: “” (empty string)**

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

Quel est le problème ? 

**⚠️ Si l'on exécute cette fonction, le statut passé à `notify` et `incrementCounter` sera toujours le même: “” (empty string)**

=> Les arguments passés à une fonction `defer` sont évalués **immédiatement**

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status) ←
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

Quel est le problème ? ⏲

⚠ Si l'on exécute cette fonction, le statut passé à **notify** et **incrementCounter** sera toujours le même: "" (empty string)

=> Les arguments passés à une fonction **defer** sont évalués **immédiatement**

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status) ← empty string ""
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

Quel est le problème ? ⏲

⚠ Si l'on exécute cette fonction, le statut passé à **notify** et **incrementCounter** sera toujours le même: "" (empty string)

=> Les arguments passés à une fonction **defer** sont évalués **immédiatement**

```
const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}
```

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

✓ Solution 1: Si l'on peut changer **notify** et **incrementCounter**

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

✓ Solution 1: Si l'on peut changer **notify** et **incrementCounter**

```

func f() error {
    var status string
    defer notify(&status)
    defer incrementCounter(&status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

```
const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}
```

## Solution 2: En utilisant une closure

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

## Solution 2: En utilisant une closure

```

i := 0
j := 0
defer func(i int) {
    fmt.Println(i, j)
}(i)
i++
j++

```

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

## Solution 2: En utilisant une closure

```

i := 0
j := 0
defer func(i int) {
    fmt.Println(i, j)
}(i)
i++
j++

```

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

## Solution 2: En utilisant une closure

```

i := 0
j := 0
defer func(i int) {
    fmt.Println(i, j)
}(i)
i++
j++

```

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

## Solution 2: En utilisant une closure

```

i := 0
j := 0
defer func(i int) {
    fmt.Println(i, j)
}(i)
i++
j++

```

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

## Solution 2: En utilisant une closure

```

i := 0
j := 0
defer func(i int) {
    fmt.Println(i, j)
}(i)
i++
j++

```

0 1

```

const (
    StatusSuccess = "success"
    StatusErrorFoo = "error_foo"
    StatusErrorBar = "error_bar"
)

func f() error {
    var status string
    defer notify(status)
    defer incrementCounter(status)

    if err := foo(); err != nil {
        status = StatusErrorFoo
        return err
    }

    if err := bar(); err != nil {
        status = StatusErrorBar
        return err
    }

    status = StatusSuccess
    return nil
}

```

## Solution 2: En utilisant une closure

```

func f() error {
    var status string
    defer func() {
        notify(status)
        incrementCounter(status)
    }()
}

if err := foo(); err != nil {
    status = StatusErrorFoo
    return err
}

if err := bar(); err != nil {
    status = StatusErrorBar
    return err
}

status = StatusSuccess
return nil
}

```

## Solution 1: Variable shadowing

```
type Customer struct {
    ID      string
    Balance float64
}

type Store struct {
    m map[string]*Customer
}

func (s *Store) storeCustomers(customers []Customer) {
    for _, customer := range customers {
        s.m[customer.ID] = &customer
    }
}

func main() {
    s := Store{m: make(map[string]*Customer)}
    s.storeCustomers([]Customer{
        {ID: "1", Balance: 10},
        {ID: "2", Balance: -10},
        {ID: "3", Balance: 0},
    })
    // ...
}
```

## Solution 1: Variable shadowing

```
type Customer struct {
    ID      string
    Balance float64
}

type Store struct {
    m map[string]*Customer
}

func (s *Store) storeCustomers(customers []Customer) {
    for _, customer := range customers {
        s.m[customer.ID] = &customer
    }
}

func main() {
    s := Store{m: make(map[string]*Customer)}
    s.storeCustomers([]Customer{
        {ID: "1", Balance: 10},
        {ID: "2", Balance: -10},
        {ID: "3", Balance: 0},
    })
    // ...
}
```

```
type Customer struct {
    ID      string
    Balance float64
}

type Store struct {
    m map[string]*Customer
}

func (s *Store) storeCustomers(customers []Customer) {
    for _, customer := range customers {
        customer := customer
        s.m[customer.ID] = &customer
    }
}

func main() {
    s := Store{m: make(map[string]*Customer)}
    s.storeCustomers([]Customer{
        {ID: "1", Balance: 10},
        {ID: "2", Balance: -10},
        {ID: "3", Balance: 0},
    })
    // ...
}
```

## Solution 2: Utilisation de l'index

```
type Customer struct {
    ID      string
    Balance float64
}

type Store struct {
    m map[string]*Customer
}

func (s *Store) storeCustomers(customers []Customer) {
    for _, customer := range customers {
        s.m[customer.ID] = &customer
    }
}

func main() {
    s := Store{m: make(map[string]*Customer)}
    s.storeCustomers([]Customer{
        {ID: "1", Balance: 10},
        {ID: "2", Balance: -10},
        {ID: "3", Balance: 0},
    })
    // ...
}
```

## Solution 2: Utilisation de l'index

```
type Customer struct {
    ID      string
    Balance float64
}

type Store struct {
    m map[string]*Customer
}

func (s *Store) storeCustomers(customers []Customer) {
    for _, customer := range customers {
        s.m[customer.ID] = &customer
    }
}

func main() {
    s := Store{m: make(map[string]*Customer)}
    s.storeCustomers([]Customer{
        {ID: "1", Balance: 10},
        {ID: "2", Balance: -10},
        {ID: "3", Balance: 0},
    })
    // ...
}
```

```
type Customer struct {
    ID      string
    Balance float64
}

type Store struct {
    m map[string]*Customer
}

func (s *Store) storeCustomers(customers []Customer) {
    for i := range customers {
        customer := &customers[i]
        s.m[customer.ID] = customer
    }
}

func main() {
    s := Store{m: make(map[string]*Customer)}
    s.storeCustomers([]Customer{
        {ID: "1", Balance: 10},
        {ID: "2", Balance: -10},
        {ID: "3", Balance: 0},
    })
    // ...
}
```

## Good Code vs Bad Code in Golang

Recently, I was asked to detail what makes a good code or a bad code in Golang. I found this [exercice](#) very interesting. Actually, interesting enough to write a post about that. To illustrate my answer, I have taken a concrete use cases I faced in the Air Traffic Management (ATM) domain. The project is available in [Github](#).

### Context

First, few words to explain the context of the implementation.

Eurocontrol is the organization managing the air traffic across Europe countries. The common network for exchanging data between Eurocontrol and an Air Navigation Service Provider (ANSP) is called AFTN. This network is mainly used to exchange two different message types: ADEXP and ICAO messages. Each message type has its own syntax but in terms of semantic, both types are equivalent (more or less). Given the context, performance must be a key element for the implementation.

This project has to provide two implementations for parsing ADEXP messages (ICAO is not managed in the frame of this exercise) based on Go:

- A bad implementation (package name: [bad](#))
- A refactored implementation (package name: [good](#))

## Go code refactoring : the 23x performance hunt

A few weeks ago, I read an article called “[Good Code vs Bad Code in Golang](#)” where the author guides us step-by-step through the refactoring of an actual business use case.

The article focuses on turning “bad code” into “good code”: more idiomatic, more legible, leveraging the specifics of the go language. But it also insists on **performance** being an important aspect of the project. This triggered my curiosity: let’s dig in!

...

The program basically reads an input file, and parses each line to populate an object in memory.

## Go code refactoring : the 23x performance hunt

A few weeks ago, I read an article called “[Good Code vs Bad Code in Golang](#)” where the author guides us step-by-step through the refactoring of an actual business use case.

The article focuses on turning “bad code” into “good code”: more idiomatic, more legible, leveraging the specifics of the go language. But it also insists on **performance** being an important aspect of the project. This triggered my curiosity: let’s dig in!

...

The program basically reads an input file, and parses each line to populate an object in memory.

Input data
